NADH Oxidase(NOX) Activity Assay Kit

Note: Take two or three different samples for prediction before test.

Operation Equipment: Spectrophotometer

Cat No: NA0818

Size: 50T/24S

Components:

Reagent I: Liquid 25 mL×1. Storage at 4℃.

Reagent II: Liquid 5 mL×1. Storage at 4℃.

Reagent III: Liquid 0.5 mL×1. Storage at -20℃.

Reagent IV: Liquid 70 mL×1. Storage at 4℃.

Reagent V: Liquid 10 mL×1. Storage at 4℃.

Reagent VI: Powder×2. Storage at -20℃. Add 9 mL of distilled water to each bottle before use. Keep the unused reagents in separate packages at -20℃.

Product Description:

NADH oxidase (NOX) (EC 1.6.99.3) exists widely in animals, plants, microorganisms and cultured cells, which can direct the oxidation of NADH to NAD under oxygen. This enzyme is not only involved in the regeneration of NAD, but also closely related to immune response.

NOX can oxidize NADH to NAD, oxidation of NADH is coupled to the reduction phase of 2,6-dichlorophenol indigo (DCPIP) and the blue DCPIP is restored to colorless DCPIP. The NOX activity can be quantified by measuring the decrease in the color development at 600 nm.

Reagents and Equipment Required but Not Provided:

Spectrophotometer, water bath, desk centrifuge, adjustable pipette, 1 mL glass cuvette, mortar/homogenizer, ice and distilled water.

Procedure:

I. Complex extraction:

Isolation of cytoplasmic and mitochondrial proteins from tissues, bacteria or cells:

1) Collecting 0.1 g of tissue or 5 million cells, add 1 mL of Extract solution and 10 μL Reagent III, grinding on ice with mortar/homogenizer.

2) Centrifuge at 600 ×g for 5 minutes at 4℃. Take the supernatant to other tube and centrifuge at 11000 g for 10 minutes at 4℃.

3) Take the supernatant to other tube. It's a cytoplasmic extract. The supernatant can be used to detect NOX activity.

4) The precipitate is mitochondria. Add 200 μL of Reagent II and 2 μL of Reagent III to the sediment and used to detect the enzyme activity of NOX. It is also used for protein concentration determination.

II. Determination

1) Preheat spectrophotometer for 30 minutes, adjust the wavelength to 600 nm, set zero with distilled water.

2) Preheat reagent IV at 37℃ water bath.

3) Add the following reagents in 1 mL glass cuvette:

Reagent	Test tube (T)	Control tube (C)
Reagent IV (μL)	700	700
Reagent V (μL)	100	100
Sample (μL)	40	40
Distilled water (μL)	-	160
Reagent VI (μL)	160	-
Operate the above reagents in the 1 mL glass cuvette in sequence. Mix thoroughly and timing after add Reagent VI, detect the absorbance at 600 nm at the time of 20 seconds record as A_{T1} or A_{C1}. Then place dishes with the reaction solution in a 37℃ water bath for 1 minutes. Take it out and wipe it clean, immediately measure the absorbance of final reaction at the time of 80s which record as A_{T2} or A_{C2}, $\Delta A_T=A_{T1}-A_{T2}$, $\Delta A_C=A_{C1}-A_{C2}$. $\Delta A=\Delta A_T-\Delta A_C$.		

III. Calculation:

Tissue protein concentration:

Unit definition: One unit of enzyme activity is defined as the amount of enzyme catalyzes the absorbance at 600 nm changed 0.01 in the reaction system per minute every milligram of protein.

NOX Activity (U/mg prot)=ΔA÷0.01×Vrv÷Cpr×Vs)÷T =2500×ΔA÷Cpr

Vrv: Total reaction volume, 1 mL;

Cpr: Supernatant sample protein concentration (mg/mL)

Vs: Sample volume (mL), 0.04 mL;

T: Reaction time (min), 1 minute;

Note:

1. Sample preparation processes should be operated at 0℃-4℃ to prevent denaturation and deactivation of enzyme.

2. Keep 37℃ of the react solution in cuvette, add 37℃ water to a beaker, put this beaker in 37℃ water bath and put the cuvette in this beaker.

3. It is better for two people to do this experiment at the same time, one for colorimetric and the other for timing to ensure the accuracy of the experimental results.

4. During the tests, keep Reagent VI on ice to avoid denaturation and deactivation.

5. It is recommended to use the sample protein concentration to calculate the enzyme activity. If the fresh weight of the sample is used for calculation, the enzyme activity of the cytoplasmic extract should be measured. The sum of supernatant and precipitation enzyme activity is the total enzyme activity.

6. Attachment: calculation formula of fresh weight of samples

Tissue weight:

Unit definition: One unit of enzyme activity is defined as the amount of enzyme catalyzes the absorbance at 600 nm changed 0.01 in the reaction system per minute every gram of tissue.

NOX Activity supernatant (U/g weight) =ΔA1÷0.01×Vrv÷(W÷Ve ×Vs)÷T =2525×ΔA1÷W

NOX Activity sediment (U/g weight) =ΔA2÷0.01×Vrv÷(W÷V_{ST}×Vs)÷T =505×ΔA2÷W

NOX Activity (U/g weight) =NOX supernatant +NOX sediment=2525×ΔA1÷W+505×ΔA2÷W

ΔA1: Supernatant absorbance;

ΔA2: Sediment absorbance;

Vrv: Total reaction volume, 1 mL;

Ve: Extract solution volume, 1.01 mL;

Vs: Sample volume (mL), 0.04 mL;

T: Reaction time (min), 1 minute;

W: Sample weight, g;

V_{ST}: Sediment heavy suspension volume, 0.202 mL.

Experimental example:

1. 0.1g of lung sample is taken for sample processing. According to the determination steps, the results showed that ΔA1 = ΔA_T- ΔA_C= (0.841-0.094) - (0.956-0.849) = 0.64, Δ A2 = ΔA_T - ΔA_C= (0.945-0.471) - (1.009-0.982) = 0.447

NOX supernatant (U/g mass) = 2525 × Δ A1 ÷ W = 2525 × 0.64÷0.1 = 16160

NOX precipitation (U/g mass) = 505×ΔA2÷W = 505×0.447÷0.1 = 2257.35

NOX (U / g mass) = NOX supernatant + NOX precipitation = 2525×ΔA1÷W + 505×ΔA2÷W

=2525×0.64÷0.1+505×0.447÷0.1= 16160 + 2257.35 = 18417.35 U/g mass.

2. Take 0.1g of leaf sample for sample treatment, and operate according to the determination steps. The results show that Δ A1= ΔAT- ΔAC= (0.875-0.812) - (0.903-0.888) = 0.048, ΔA2 = ΔAT- ΔAC= (0.919-0.868) - (0.91-0.879) = 0.02

NOX supernatant (U/g mass) = 2525×ΔA1÷W = 2525×0.048÷0.1 = 1212

NOX precipitation (U / g mass) = 505×ΔA2÷W = 505×0.02÷0.1 = 101

NOX (U / g mass) = NOX supernatant + NOX precipitation = 2525×ΔA1÷W + 505×ΔA2÷W

=2525×0.048÷0.1 + 505×0.02÷0.1 = 1313 U/g mass.
